

# Deconstructing the Monolith

Designing Software that Maximizes Developer  
Productivity

Kirsten Westeinde  
Senior Software Engineer

# Agenda

1. Define monoliths and microservices
2. Analyze pros & cons
3. Introduce a third option
4. Conclusion: is there a *right* choice?

# Monolith

“A software system in which functionally distinguishable aspects are all interwoven, rather than containing architecturally separate components.”

# Microservices

“Suite of independently deployable, small, modular services in which each service runs a unique process and communicates through a well-defined, lightweight mechanism to serve a business goal”

# Monoliths

Pros	Cons
<ul style="list-style-type: none"><li>• The code is all in one place</li><li>• One test/deployment pipeline</li><li>• All data is available everywhere</li><li>• One infrastructure</li></ul>	<ul style="list-style-type: none"><li>• Slow tests</li><li>• New code having unexpected repercussions</li><li>• Need to understand the entire codebase</li></ul>

# Microservices

## Pros

- Each service is lightweight and has one clear responsibility
- Individuals/teams can work on separate services
- Individual systems are easily understandable
- Services can scale independently

## Cons

- Many different test/deployment pipelines
- Infrastructural overhead for each service
- Network communication needed between services
- Data not always available where you need it
- Large refactors can be tedious

## EXPECTED BENEFITS OF MODULAR PROGRAMMING

The expected benefits of modular programming fall into three classes:

- (1) managerial -- development time could be shortened because separate groups would work on each module with little need for communication (and little regret afterward that there had not been more communication);
- (2) product flexibility -- it was hoped that it would be possible to make quite drastic changes or improvements in one module without changing others;
- (3) comprehensibility -- it was hoped that the system could be studied a module at a time with the result that the whole system could be better designed because it was better understood.

**Is there a happy medium?**

**Modular Monolith**

# Monoliths

Pros	Cons
<ul style="list-style-type: none"><li>• The code is all in one place</li><li>• One test/deployment pipeline</li><li>• All data is available everywhere</li><li>• One infrastructure</li></ul>	<ul style="list-style-type: none"><li>• Slow tests</li><li>• New code having unexpected repercussions</li><li>• Need to understand the entire codebase</li></ul>

# Modular Monoliths

Pros	Cons
<ul style="list-style-type: none"><li>• The code is all in one place</li><li>• One test/deployment pipeline</li><li><del>• All data is available everywhere</del></li><li>• One infrastructure</li></ul>	<ul style="list-style-type: none"><li><del>• Slow tests</del></li><li><del>• New code having unexpected repercussions</del></li><li><del>• Need to understand the entire codebase</del></li></ul>

# Microservices

## Pros

- Each service is lightweight and has one clear responsibility
- Individuals/teams can work on separate services
- Individual systems are easily understandable
- Services can scale independently

## Cons

- Many different test/deployment pipelines
- Data not always available where you need it
- Infrastructural overhead for each service
- Network communication needed between services
- Large refactors can be tedious

# Modular Monoliths

## Pros

- Each ~~service~~ (module) is lightweight and has one clear responsibility
- Individuals/teams can work on separate ~~services~~ (modules)
- Individual systems are easily understandable
- ~~Services can scale independently~~

## Cons

- ~~Many different test/deployment pipelines~~
- Data not always available where you need it
- ~~Infrastructural overhead for each service~~
- ~~Network communication needed between services~~
- ~~Large refactors can be tedious~~

# Let's talk implementation details

1. Namespace
2. Untangle
3. Enforce boundaries between modules
